

5-5a Vee Dipole Mounted over Finite Ground Planes

Tilting the poles of a dipole into a vee gives us another design parameter. Section 5-4a shows when the poles are tilted down toward a large ground (infinite in 5-4a) we broaden the beam and eliminate the *E*-plane pattern null. This concept is useful when considering an element in an array. This section considers a Vee dipole mounted over finite ground planes. We can analyze the problem using GTD with its edge diffractions, PO with additional currents excited on the finite ground planes, MoM where the additional currents on the finite ground plane that interact with the currents on the dipoles, or a volumetric method using FDTD or FEM. Since altering the currents on a dipole which can be found using MoM, FDTD or FEM have little effect on its pattern, the results below were computed using PO. A more complete analysis will change these results very little and the patterns given below can serve as a design starting guide. As the ground plane shrinks we lose control of pattern. We end with the vee dipole over a long cylinder to model it mounted over a utility pole or tower. Of course, other mounting structures modify the pattern.

Figures 2 and 3 illustrate two examples of Vee dipoles mounted over 3λ square ground plane with nearly equal beamwidths in the principal planes. These are similar to the tilted vee dipole over an infinite ground plane. Figure 4 shows the broadside dip and spread in the H -plane as the dipole is raised above 0.25λ that reduces as the dipole is tilted into the vee (Figure 5).

Table 5 illustrates that when the ground plane shrinks to 1λ it can no longer significantly broaden the beam in the E -plane when the vee dipole tilt increases. However, Figure 13 shows a pattern with similar beams in the principal planes.

The dipole tilt has little effect on the *E*-plane beamwidth but the narrow width in the *H*-plane does not block the pattern and wide beams are formed.

Dual Resonant Loop Ground Plane

Figure 5-53 illustrates the geometry of a dual resonant loop ground plane consisting of 1λ and 2λ loops where the total width of the ground plane is $\lambda/2$. It is interesting to compare this with the $\lambda/2$ square ground plane.

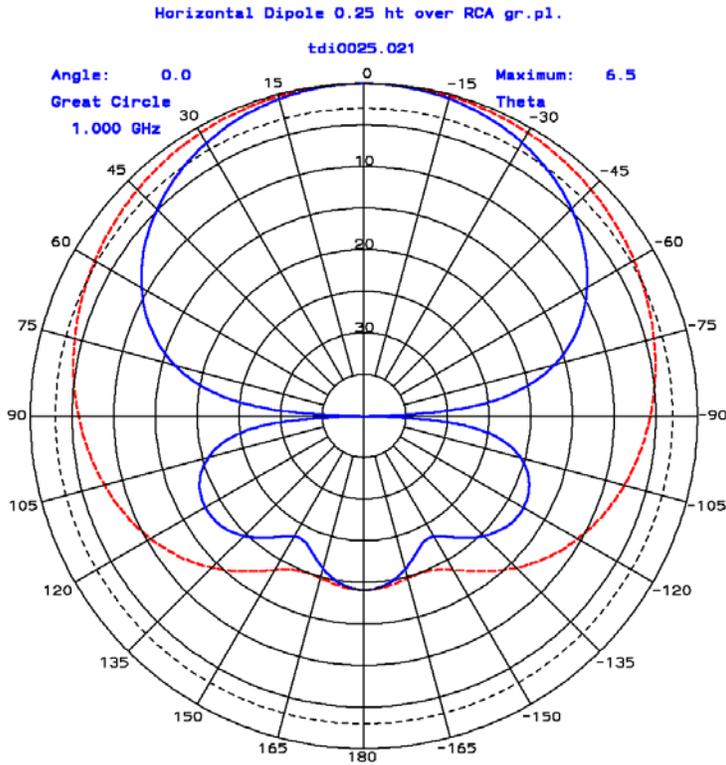

Figure 15 Horizontal Dipole 0.25λ over $\lambda/2$ wide Dual Resonant Loop *E*-plane blue (solid) *H*-plane red (dashed)

The F/B, Front/Back, of the $\lambda/2$ square ground plane is only about 8 dB while the dual resonant loop behind the dipole produces about 19 dB F/B when the dipole is spaced $\lambda/4$. Figure 16 demonstrates that the F/B increases to 25 dB for a dipole spaced 0.20λ . Tilting the vee dipole to 45° , Figure 17, reduces the F/B from 25 dB to 15 dB and illustrates that the F/B is sensitive to the vee dipole tilt, although F/B is improved compared to the square ground plane. Table 7 gives the beamwidth variation for 0.20λ and 0.25λ heights versus tilt and demonstrates that tilt has little effect on the beamwidth for a small resonant loop ground similar to the solid ground plane.

Vee Dipole Mounted over Wedge Ground Plane

We may broaden the *E*-plane beamwidth of a vee dipole by mounting it over a ground plane split in the middle and tilted down away from the dipole in the *E*-plane. The tilted currents in the ground plane fill-in the null and spread the pattern. Figure 18 of a horizontal dipole spaced $\lambda/4$ above the ridge of a wedge with 1λ sides tilted down 15° with an *H*-plane width of 2λ illustrate the wide *E*-plane beam without a null.

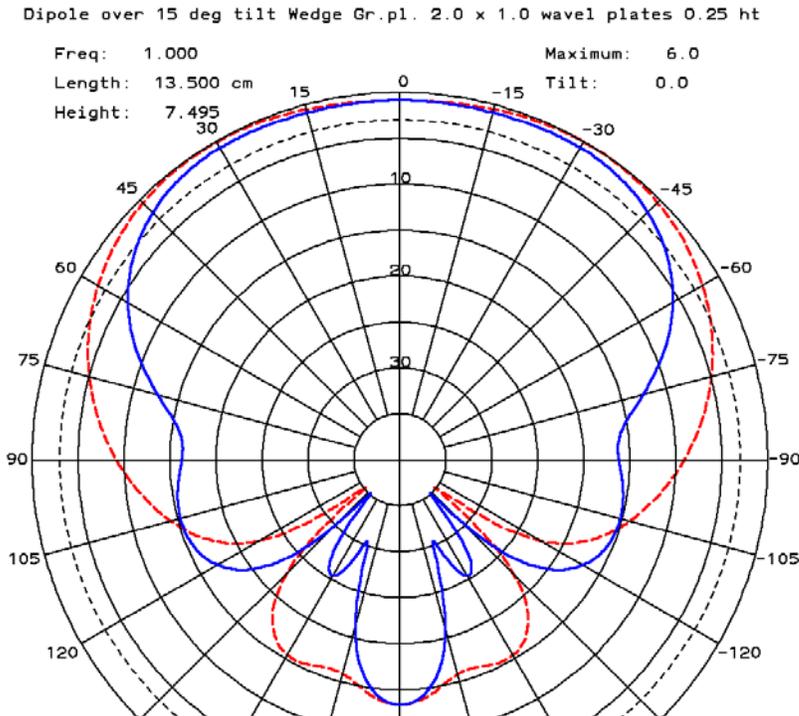

Figure 18 Horizontal Dipole 0.25λ over Wedge Ground Plane 15° 1λ sides 2λ *H*-plane width *E*-plane blue (solid) *H*-plane red (dashed)

Tilting the vee dipole to 45° over the 15° wedge produces almost equal beams in the principal planes, as shown in Figure 19.
